

TNE20003 - Internet and Cybersecurity for Engineering Applications

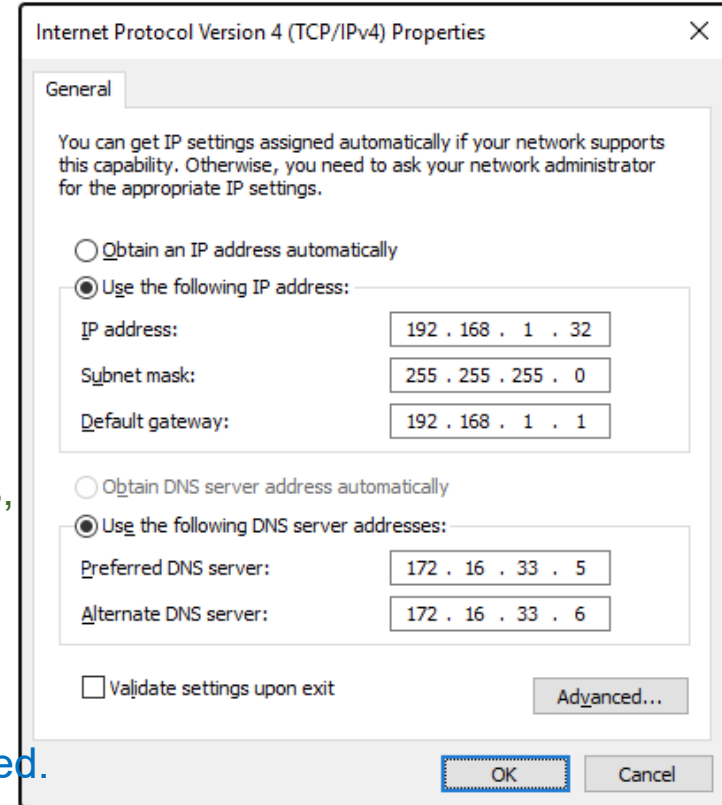

DHCP (Dynamic Host Configuration Protocol) & NAT (Network Address Translation)

Static and Dynamic Addressing

Static and Dynamic Addressing

- IPv4 addresses can be assigned either statically or dynamically.
- With a static assignment, the host IPv4 address must be configured manually, together with subnet mask, default gateway, and DNS server address.
- Static addresses are typically assigned for printers, servers, and other networking devices that need to retain a fixed IP address to provide services.
- Static assignment can be time consuming to implement. It is prone to errors because manual configuration is required.

Internet Protocol Version 4 (TCP/IPv4) Properties

General

You can get IP settings assigned automatically if your network supports this capability. Otherwise, you need to ask your network administrator for the appropriate IP settings.

☐ Obtain an IP address automatically

☒ Use the following IP address:

IP address: 192 . 168 . 1 . 32

Subnet mask: 255 . 255 . 255 . 0

Default gateway: 192 . 168 . 1 . 1

☐ Obtain DNS server address automatically

☒ Use the following DNS server addresses:

Preferred DNS server: 172 . 16 . 33 . 5

Alternate DNS server: 172 . 16 . 33 . 6

☐ Validate settings upon exit

Advanced...

OK Cancel

Static Addressing

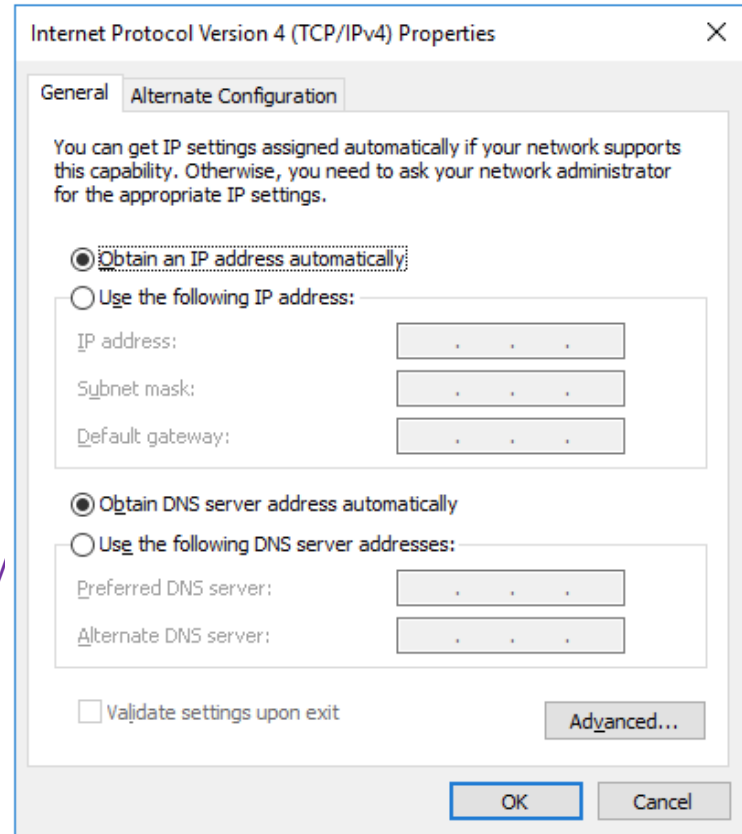

- Static routes on a router.
 - Placed into the router to allow it to have paths to all of the different networks/subnets in their system.
 - Eg on R3 you would have *"ip route 192.168.1.0 255.255.255.0 172.20.0.2"*
 - & *"ip route 192.168.2.0 255.255.255.0 172.20.0.2"*
 - & *"ip route 172.19.0.0 255.255.0.0 172.20.0.2"*
 - &

Dynamic IPv4 Address Assignment

Dynamic Addressing

- IPv4 addresses can be dynamically assigned to end devices through an application protocol known as Dynamic Host Configuration Protocol (DHCP).
- DHCP automatically assigns addressing information such as IPv4 address, subnet mask, default gateway, and other configuration information.
- Benefits of using DHCP include:
 - Reduces the burden on network support staff and virtually eliminates entry errors.
 - A dynamic IP address is not permanently assigned to a host but is only leased for a period of time. This means when that host stops being used then the address goes back into the pool.

Internet Protocol Version 4 (TCP/IPv4) Properties

General Alternate Configuration

You can get IP settings assigned automatically if your network supports this capability. Otherwise, you need to ask your network administrator for the appropriate IP settings.

☒ Obtain an IP address automatically

☐ Use the following IP address:

IP address:

Subnet mask:

Default gateway:

☒ Obtain DNS server address automatically

☐ Use the following DNS server addresses:

Preferred DNS server:

Alternate DNS server:

☐ Validate settings upon exit

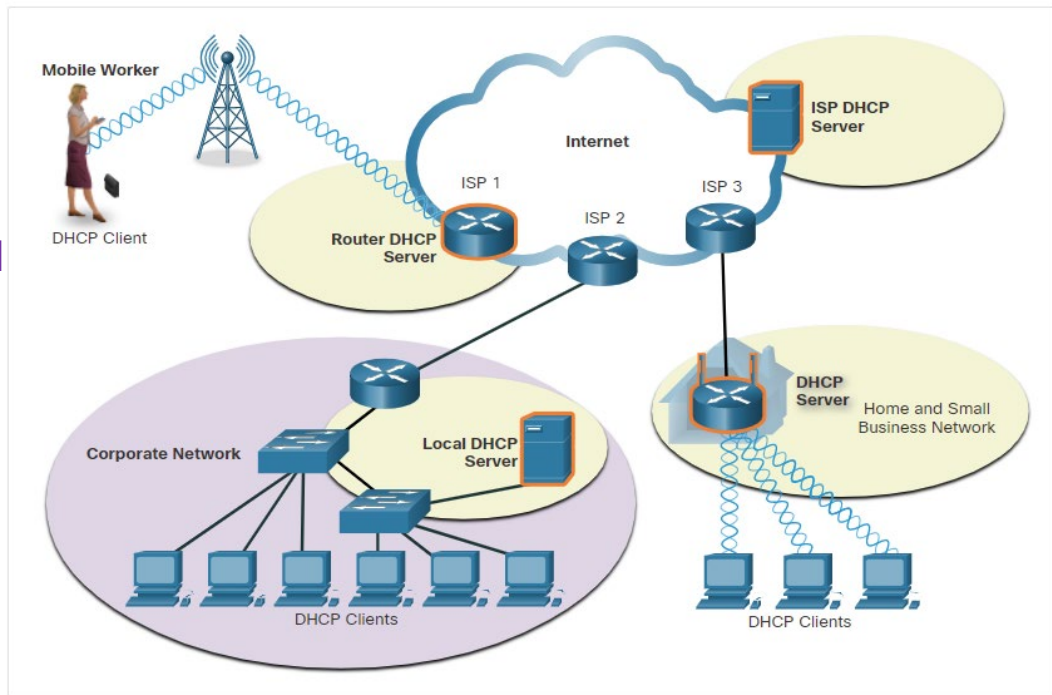

Advanced...

OK Cancel

DHCP Servers

Dynamic Addressing

- A device can be a DHCP server if it is running the DHCP service software.
- DHCPv4 servers are typically connected to a LAN because it uses broadcast. DHCPv4 servers deployed outside of a LAN will require relay service.
- In a home network or SOHO, a wireless router provides DHCP service to end devices. It is also a DHCP client to get IPv4 address from ISP.

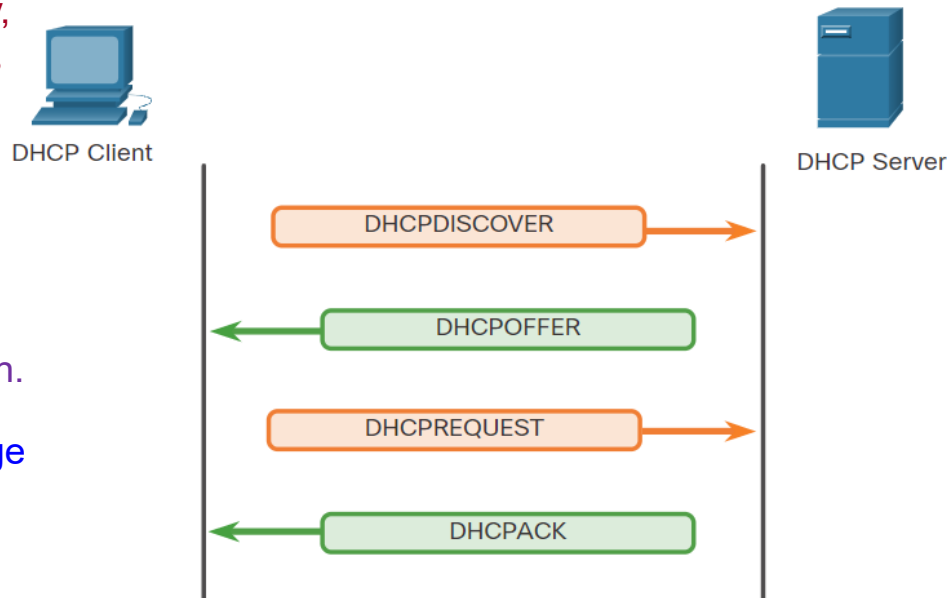

DHCPv4 Configuration

DHCPv4 Configuration

When a host is configured using DHCP, it will try to obtain an IPv4 address, subnet mask, default gateway, and other options from a DHCP server. The process is as follows:

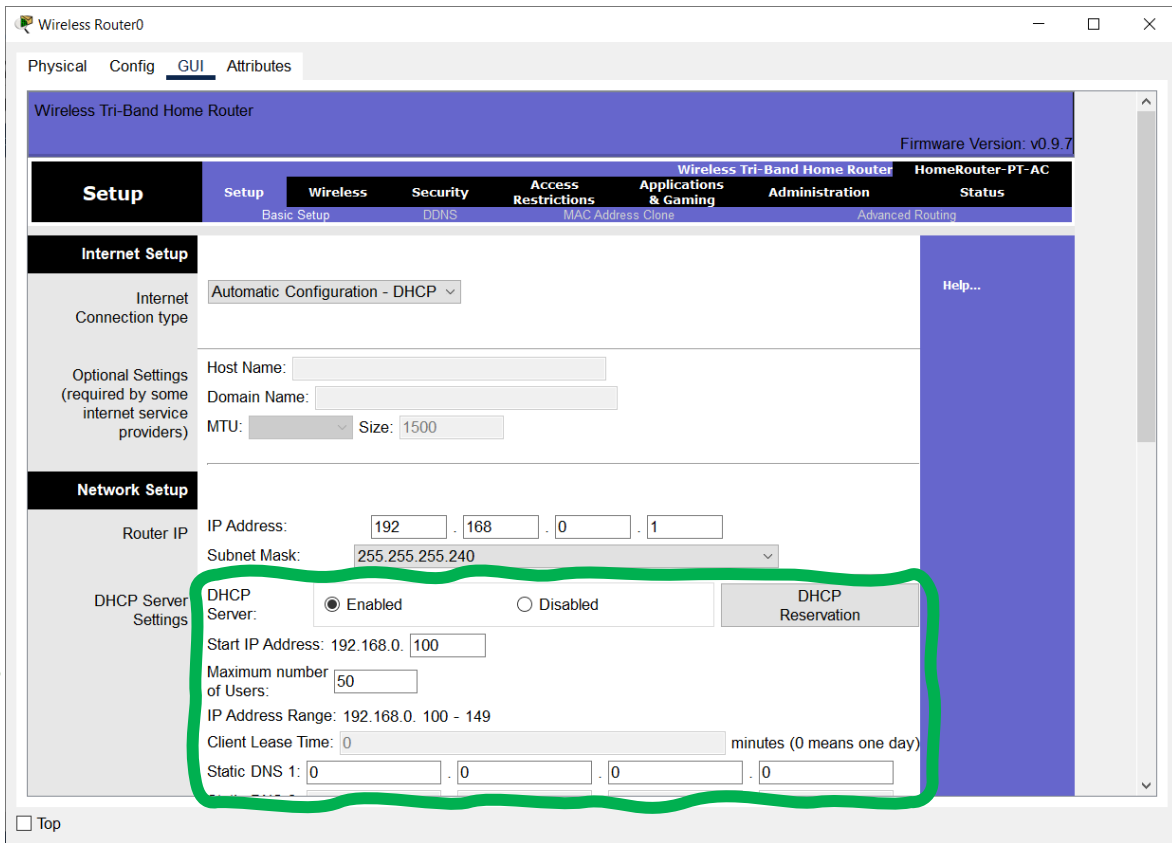

1. The client sends a **DHCPDISCOVER** message using broadcast.
2. A DHCP server responds with a **DHCPOFFER** message with a set of IPv4 addressing information.
3. The client then sends a **DHCPREQUEST** message to request the use of IPv4 addressing information offered by the DHCP server.
4. The DHCP server responds with a **DHCPACK** message to grant the request from the client.

DHCP Service Configuration

DHCPv4 Configuration - Basic or SOHO

- To configure a home wireless router, access its graphical web interface by opening the browser and entering the router default IPv4 address: 192.168.0.1 in the IP Address field.
- The IPv4 address of 192.168.0.1 and subnet mask of 255.255.255.0 are the defaults for the internal router interface.
This is the default gateway for all hosts on the local network. Ensure the DHCP server is enabled.
- Specify the DHCP IPv4 address **range** with a **starting address** and the **number** of addresses to be assigned. (do not use 192.168.0.1 because the router is already assigned this address)

DHCP Summary

- IPv4 addresses can be assigned either statically or dynamically.
- A static assignment must be manually configured on a host.
- When using static IPv4 addressing, maintain an accurate list of which IPv4 addresses are assigned to which devices is difficult.
- Dynamic addressing uses DHCP to provides automatic assignment of addressing information such as IPv4 address, subnet mask, default gateway, and other IPv4 networking parameters.
- DHCP can allocate IP addresses for a configurable period of time, called a lease period.
- Many networks use both DHCP and static addressing. DHCP is used for general purpose hosts, such as end user devices. Static addressing is used for network devices, such as gateway routers, switches, servers, and printers.
- A DHCPv4 client and DHCPv4 servers use DHCP messages to initiate and complete a dynamic IPv4 addressing assignment.

Network Boundaries

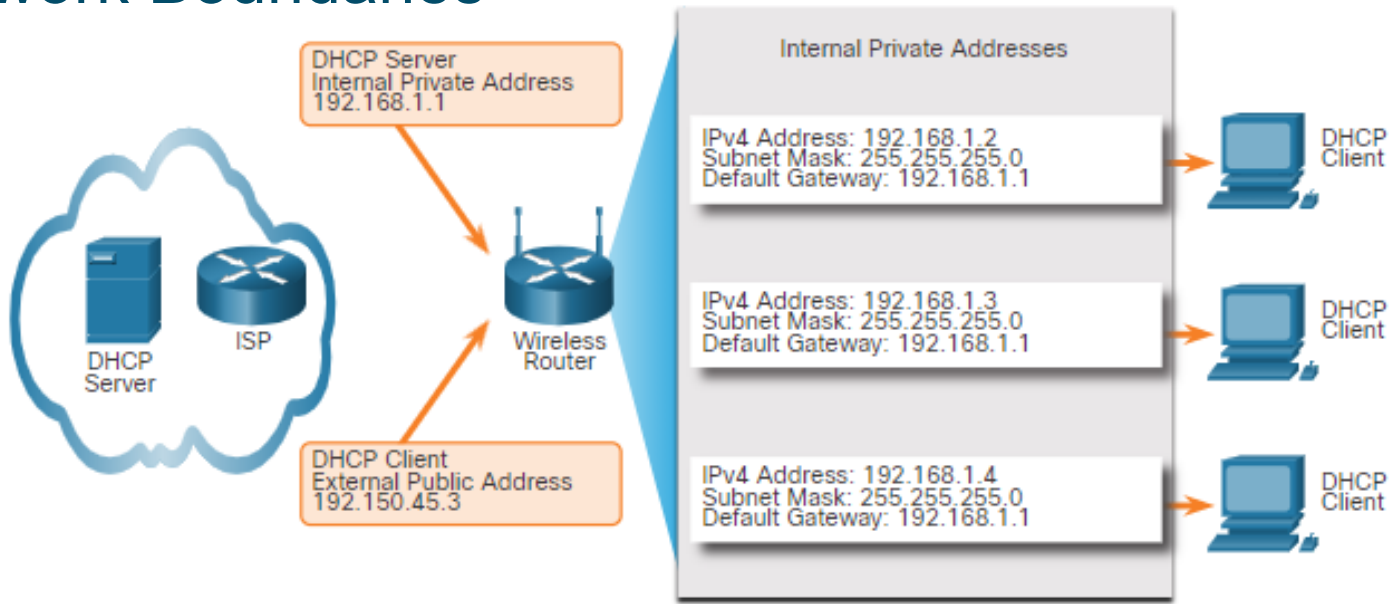

Network Boundaries

- Routers are used to connect networks.
- Each router interface connects to a separate network.
- The IPv4 address assigned to the interface is the default gateway address for all hosts connected to that same network.
- Hosts commonly get an IPv4 address using DHCP.

Routers as Boundaries Between Networks

Network Boundaries

- A wireless router commonly provides IP addressing information for local internal hosts.
- A router that connects to the internet commonly gets addressing information using DHCP from the internet provider.

IPv4 Issues

IPv4 limitations & Temporary Solutions:

- **IPv4 address depletion** – We have basically run out of IPv4 addressing.
- **Lack of end-to-end connectivity** – To make IPv4 survive this long, private addressing and NAT were created. This ended direct communications with public addressing.
- **Increased network complexity** – Network Address Translation was meant as temporary solution and creates issues on the network as a side effect of manipulating the network headers addressing. NAT causes latency and troubleshooting issues.

© 2016 Cisco and/or its affiliates. All

New Solution to IPv4 problem is IPv6

- IPv6 was developed by Internet Engineering Task Force (IETF).
- IPv6 overcomes the limitations of IPv4.
 - 4 billion IPv4 addresses
4,000,000,000
 - 340 undecillion IPv6 addresses
340,000,000,000,000,000,000,000,000,000,000,000,000,000,000,000,000
 - Current World Population - March 2021
7,852,291,814
- Improvements that IPv6 provides:
 - Increased address space – 128-bit address, not 32-bits
 - Improved packet handling – simplified header with fewer fields
 - Eliminates the need for NAT – since there is a huge amount of addressing, there is no need to use private addressing internally and be mapped to a shared public address...

IPv4 Issues

■ The Need for IPv6

- Depletion of IPv4 address space
- Internet of Everything

■ IPv4 and IPv6 Coexistence

- Dual Stack – IPv4 and IPv6 on the same network
- Tunneling – IPv6 packets inside IPv4 packets
- Translation - IPv6 packet is translated to an IPv4 packet, and vice versa.

Network Address Translation - explained

IPv4 Private Address Space

A number of companies found that most of their communications was internal so no need to buy real external IP addresses.

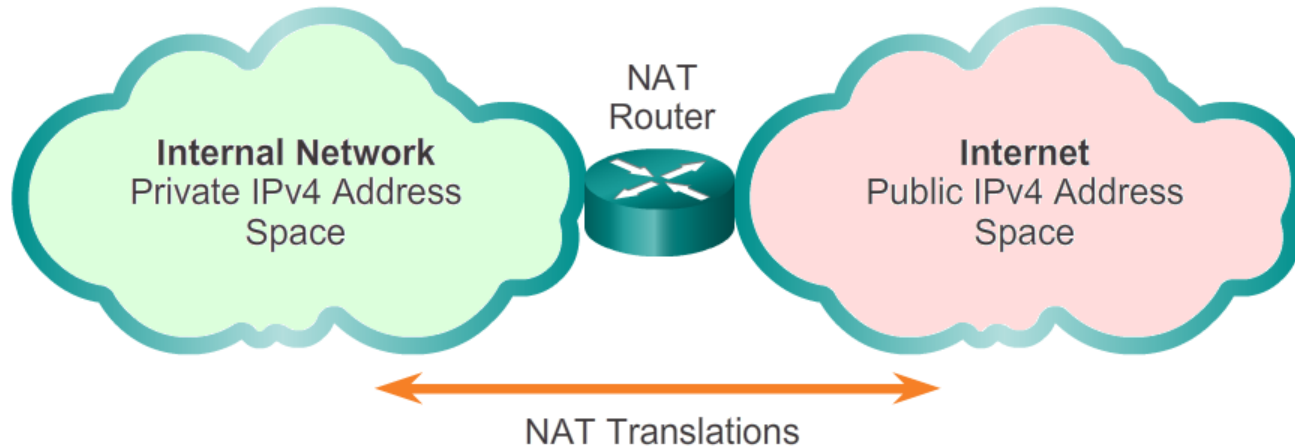

Hence the central bodies decided to provide Private address spaces for internal use ONLY and NOT to be advertised on the real internet.

Private Internet addresses are defined in RFC 1918:		
Class	RFC 1918 Internal Address Range	CIDR Prefix
A	10.0.0.0 - 10.255.255.255	10.0.0.0/8
B	172.16.0.0 - 172.31.255.255	172.16.0.0/12
C	192.168.0.0 - 192.168.255.255	192.168.0.0/16

IPv4 Private Address Space

As networking evolved so too did the need to communicate from these private address spaces to the outside world. This meant there was a need for more IPv4 addresses which were now scarce.

Hence the need for Network Address Translation (NAT)

What is NAT?

- NAT is a process used to translate network addresses.
- NAT's primary use is to conserve public IPv4 addresses.
- NAT is usually implemented at border network devices, such as firewalls or routers.
- NAT allows the networks to use private addresses internally, only translating to public addresses when needed.
- Devices within the organization can be assigned private addresses and operate with locally unique addresses.
- When traffic must be sent or received to or from other organizations or the Internet, the border router translates the addresses to a public and globally unique address.

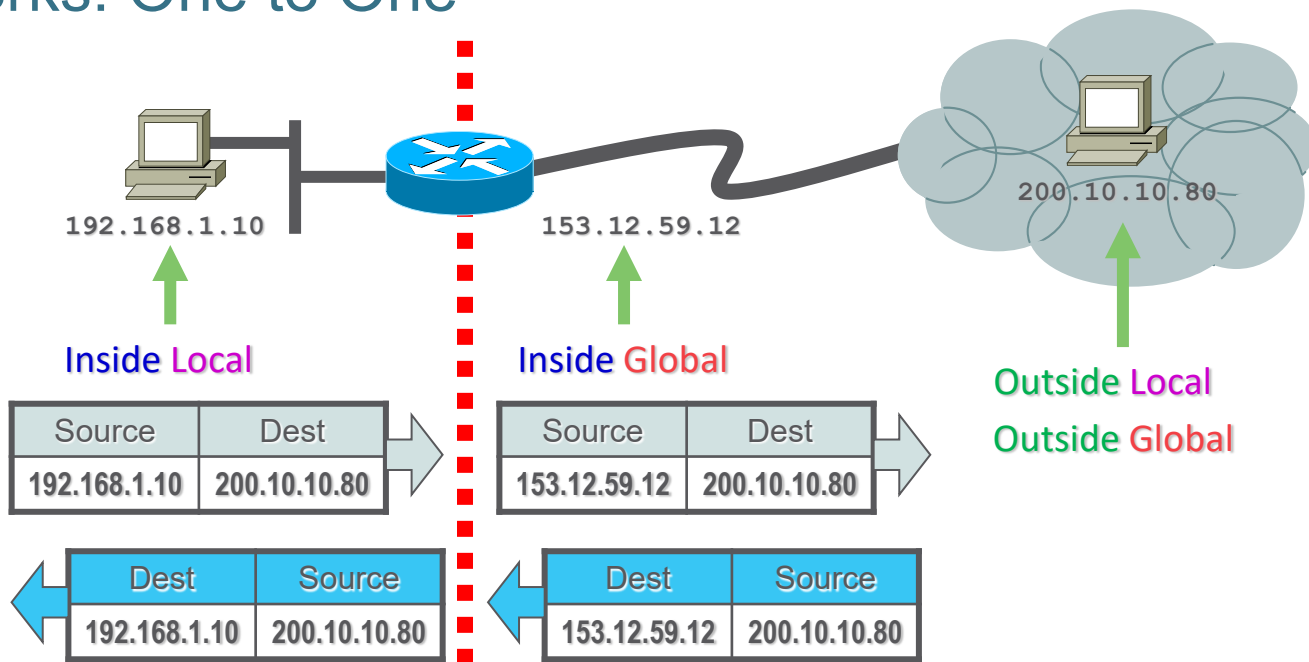

- **Inside Local Address** – The IP address assigned to a host on the inside network. Usually not an IP address assigned by the (NIC) or service provider. This address are typically private address.
- **Inside Global Address** – A legitimate IP address assigned by the NIC or service provider that represents one or more inside local IP addresses to the outside world.
- **Outside Local Address** – The IP address of an outside host as it known to the hosts in the inside network.
- **Outside Global Address** – The IP address assigned to a host on the outside network. The owner of the host assigns this address.

Inside or Outside of your Administration control !
NOT your inside or outside interfaces !!!

NAT Characteristics

How it Works: One to One

```
Router# show ip nat translations
```

```
Pro Inside Global    Inside Local    Outside Local    Outside Global
--- 153.12.59.12    192.168.1.10    200.10.10.80    200.10.10.80
```

Major NAT and PAT Features.

Network Address Translation

- NAT translations can be either Dynamic or Static.
- Static NAT is designed to allow one-to-one mapping of local and global addresses.
- Useful for hosts which must have a consistent address that is accessible from the Internet. Such hosts may be enterprise servers or networking devices.
- Dynamic NAT is designed to map a private IP address to a public address. Any IP address from a pool of public IP addresses is assigned to a network host.

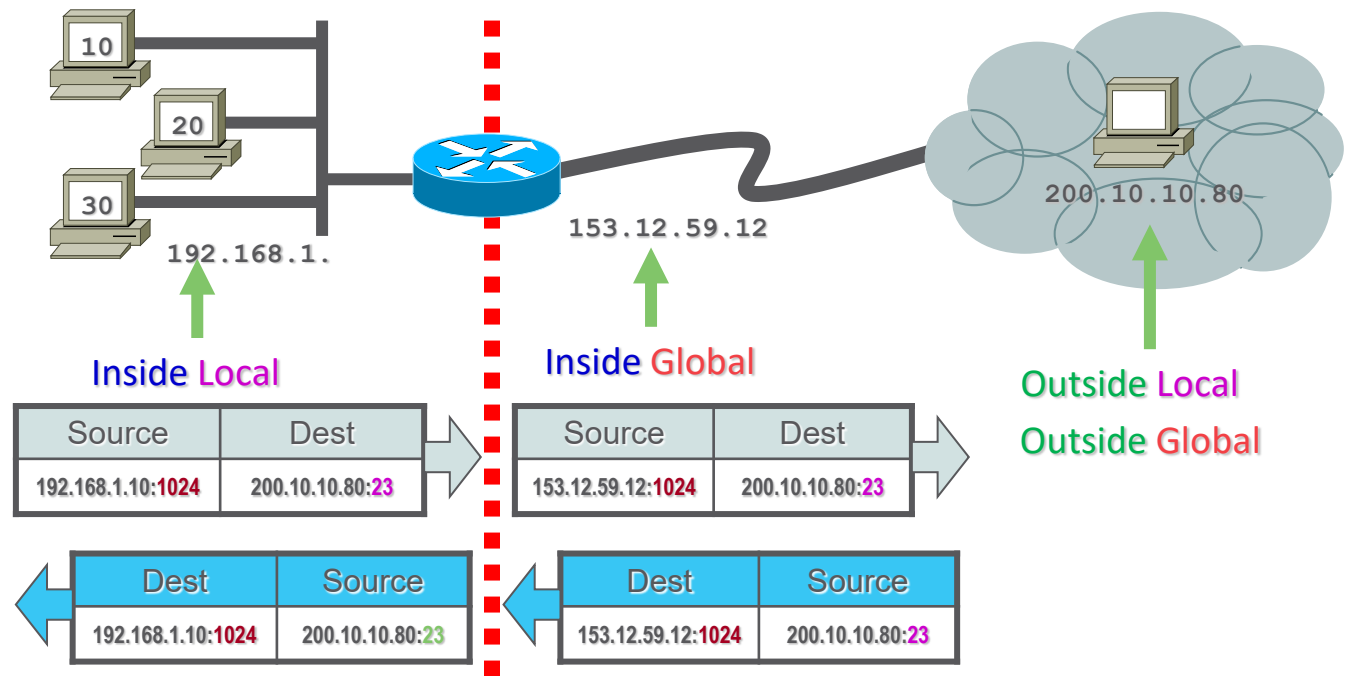

Major NAT and PAT Features...

Port Address Translation

- Overloading, or Port Address Translation (PAT), maps multiple private IP addresses to a Single public IP address.
- The multiple addresses can be mapped to a single address because each private address is tracked by its port number.
- The port number is encoded in 16 bits (65,535 ports per IP address). Practically, ports per single IP address is 4,095.
- PAT will attempt to preserve the original source port. If the source port is in use, the first available port is assigned.
- When there are no more ports available, PAT moves to the next IP address to try to allocate the original source port again, until all IPs are saturated (4095 x Total IPs in pool).

How it Works: Many to One

```
Router# show ip nat translations
```

Pro	Inside Global	Inside Local	Outside Local	Outside Global
tcp	153.12.59.12:1024	192.168.1.10:1024	200.10.10.80:23	200.10.10.80:23
tcp	153.12.59.12:1025	192.168.1.20:1024	200.10.10.80:23	200.10.10.80:23
udp	153.12.59.12:1026	192.168.1.30:1024	200.10.10.80:53	200.10.10.80:53

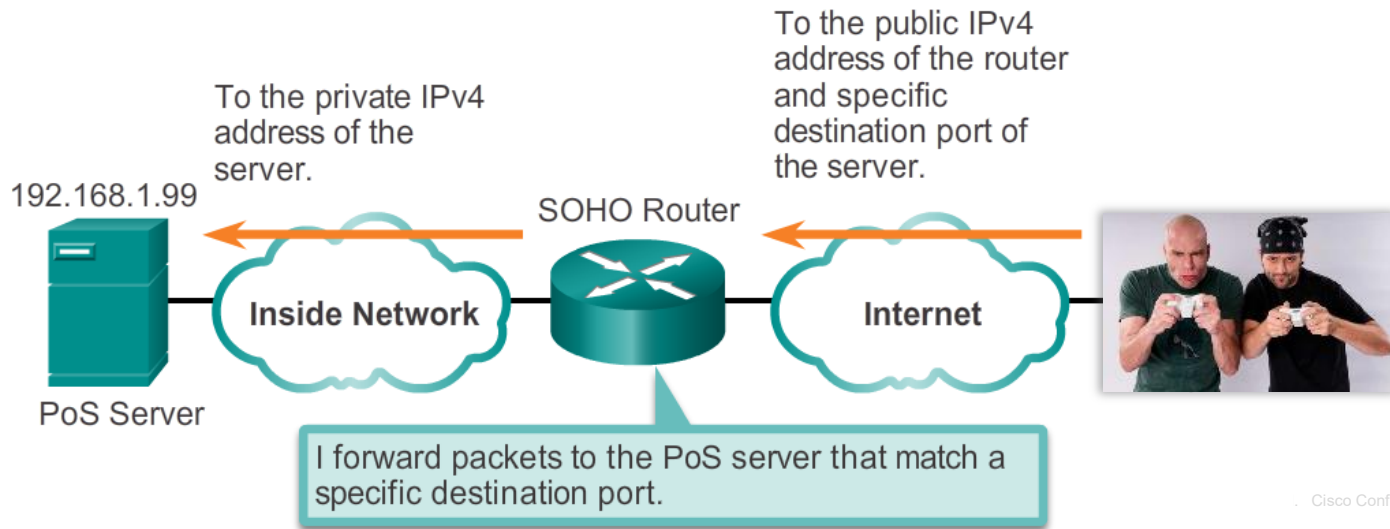

Major NAT and PAT Benefits.

- Eliminates re-assigning each host a new IP address when changing to a new ISP.
- NAT eliminates the need to re-address all hosts that require external access, saving time and money.
- Conserves addresses through application port-level multiplexing.
With PAT, internal hosts can share a single public IP address for all external communications.
- Protects network security. Because private networks do not advertise their addresses or internal topology.

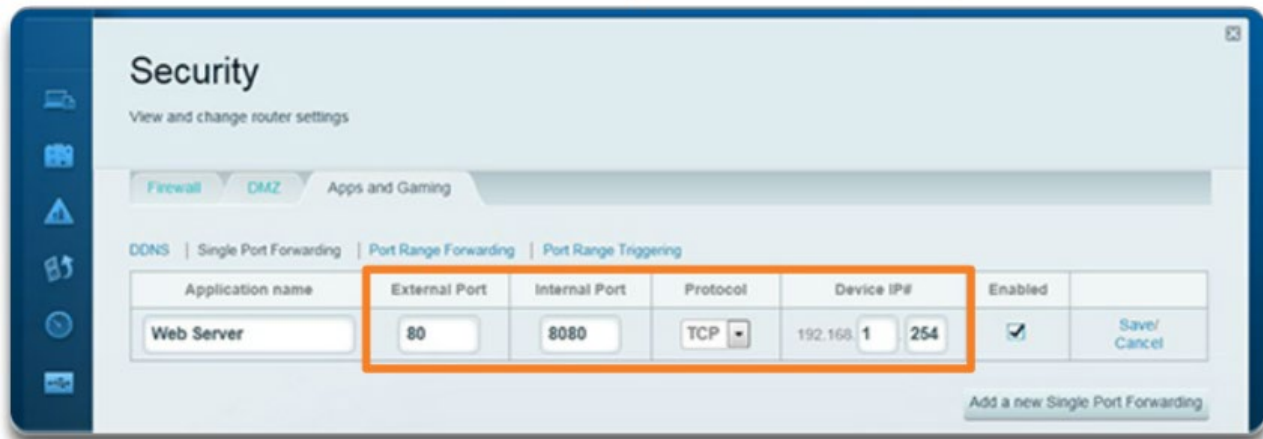

Port Forwarding

- Port forwarding is the act of forwarding a network port from one network node to another.
- A packet sent to the public IP address and port of a router can be forwarded to a private IP address and port in inside network.
- Port forwarding is helpful in situations where servers have private addresses, not reachable from the outside networks.

Port Forwarding

SOHO Example

...and for Cisco IOS:-

```
ip nat inside source static tcp 192.168.1.254 8080 209.165.200.225 80
ip nat inside source static tcp 192.168.1.254 8080 interface Fa0/0 80
```

IPv4 and NAT/PAT

- Routers create network boundaries.
- The IP address on a router interface that connects to an internal (inside) network is the default gateway address for all hosts on that same network.
- The IP address assigned to the internet side of a router such as a wireless router is the external, or outside, network.
- Network Address Translation (NAT) is used to convert private IP addresses used on an internal network to a public (global) address that can be routed through the internet.
- With PAT one single public address can be used for many internal hosts.
- Public IPv4 addresses have been scarce for some time.
- An IPv6 address is 128 bits and does not require NAT.
- Dual stack allows IPv4 and IPv6 networks to coexist.
- Tunneling is a method used to transport an IPv6 packet over an IPv4 network.
